## Experiment No. 1

**Title:** Program to perform arithmetic operations by accepting values from users

**Aim:** To write a program to perform arithmetic operations by accepting values from users

**Objective:** To introduce basic concepts in Python

**Theory:**

### What is Python?

Python is a popular programming language. It was created by Guido van Rossum, and released in 1991.

It is used for:

- web development (server-side),
- software development,
- mathematics,
- system scripting.

What can Python do?

- Python can be used on a server to create web applications.
- Python can be used alongside software to create workflows.
- Python can connect to database systems. It can also read and modify files.

# Vidyavardhini's College of Engineering & Technology

## Department of Computer Engineering

---

- Python can be used to handle big data and perform complex mathematics.
- Python can be used for rapid prototyping, or for production-ready software development.

### Why Python?

- Python works on different platforms (Windows, Mac, Linux, Raspberry Pi, etc).
- Python has a simple syntax similar to the English language.
- Python has syntax that allows developers to write programs with fewer lines than some other programming languages.
- Python runs on an interpreter system, meaning that code can be executed as soon as it is written. This means that prototyping can be very quick.
- Python can be treated in a procedural way, an object-oriented way or a functional way.

### Good to know

- The most recent major version of Python is Python 3, which we shall be using in this tutorial. However, Python 2, although not being updated with anything other than security updates, is still quite popular.
- In this tutorial Python will be written in a text editor. It is possible to write Python in an Integrated Development Environment, such as Thonny, Pycharm, Netbeans or Eclipse which are particularly useful when managing larger collections of Python files.

### Python Syntax compared to other programming languages

- Python was designed for readability, and has some similarities to the English language with influence from mathematics.
- Python uses new lines to complete a command, as opposed to other programming languages which often use semicolons or parentheses.
- Python relies on indentation, using whitespace, to define scope; such as the scope of loops, functions and classes. Other programming languages often use curly-brackets for this purpose.

**Arithmetic operators** are used to perform mathematical operations like addition, subtraction, multiplication and division.

There are 7 arithmetic operators in Python :

1. Addition
2. Subtraction
3. Multiplication
4. Division
5. Modulus
6. Exponentiation
7. Floor division

# Vidyavardhini's College of Engineering & Technology

### Code:

```
num1 = float(input("Enter the first number: "))
num2 = float(input("Enter the second number: "))

sum1 = num1 + num2
mul1 = num1 * num2
div1 = num1 / num2
exp = num1 ** num2
fd = num1 // num2
mod = num1 % num2

# Fix the print statement
print("The sum of {0} and {1} is {2}".format(num1, num2, sum1))
print("The multiplication of {0} and {1} is {2}".format(num1, num2, mul1))
print("The division of {0} and {1} is {2}".format(num1, num2, div1))
print("The exponential of {0} and {1} is {2}".format(num1, num2, exp))
print("The floor division of {0} and {1} is {2}".format(num1, num2, fd))
print("The modulus of {0} and {1} is {2}".format(num1, num2, mod ))
```

### Output:-

```
C:\Users\student\Desktop>python exp1.py
Enter the first number: 34
Enter the second number: 89
The sum of 34.0 and 89.0 is 123.0
The multiplication of 34.0 and 89.0 is 3026.0
The division of 34.0 and 89.0 is 0.38202247191011235
The exponential of 34.0 and 89.0 is 2.002735595342647e+136
The floor division of 34.0 and 89.0 is 0.0
The modulus of 34.0 and 89.0 is 34.0
```

**Conclusion:** Arithmetic operators have been implemented.
